

# Problem 1

---

First find the min cut of  $G$  in polynomial time. Suppose this min cut is  $C$ , and has edge  $e_1, e_2, \dots, e_k \in C$ .

For each edge  $e_i$ , increase its capacity by 1 and name this new graph  $G_i$ . First find the min cut of  $G_i$  in polynomial time. Suppose this min cut is  $C_i$ .

- if the volume of  $C$  = the volume of  $C_i$ , then it means there exist another min cut which doesn't include edge  $e_i$ . Therefore  $G$  doesn't have a unique min cut.
- if the volume of  $C <$  the volume of  $C_i$  for all  $i$ , then  $G$  has a unique min cut.

The number of edges in  $C$  is  $O(E)$ , therefore we run the algorithm to find min cut at most  $O(E) + 1 = O(E)$  times. Since the algorithm to find min cut runs in polynomial time, this whole algorithm runs in polynomial time.

---

# Problem 2

---

construct the flow network, name this graph  $G$ :

1. Let the cell  $(1, 1)$  be the source node  $s$ .
2. Let the cell  $(n, m)$  be the sink node  $t$ .
3. For each cell  $(x, y)$  in the grid:
  - If cell  $(x, y)$  is an obstacle, then no node is connected to or from it.
  - Otherwise, create edges to adjacent cells  $(x, y + 1)$  and  $(x + 1, y)$  with capacities 1 if those cells are within the grid bounds and not obstacles.

After the construction, run the polynomial time algorithm to find the max flow value  $f$  on this graph  $G$ . The answer will be  $f$ .

---

# Problem 3

---

Construct a flow network:

1. Each menu item  $i$  corresponds to a node  $v_i$ .
2. Each customer  $j$  corresponds to a node  $u_j$ .
3. There is a source node  $s$  and a sink node  $t$ .
4. Connect the source node  $s$  to each customer node  $u_j$  with an edge of capacity 1.
5. Connect each customer node  $u_j$  to the menu items they are willing to order with an edge of capacity 1.
6. Connect each menu item node  $v_i$  to the sink node  $t$  with an edge of capacity  $d_i$ .

Find the  $s - t$  max flow on this graph. The maximum number of customer we can serve will be the value of max flow.

---

## Problem 4

---

1. Convert the vertex capacities to edge capacities:

1. Split every vertex  $v$  into two vertices  $v_{in}$  and  $v_{out}$
2. Create an edge  $(v_{in}, v_{out})$  with capacity  $c_v$ , which is the capacity of  $v$ .
3. Connect all the original incoming edges to  $v_{in}$  and all the original outgoing edges to  $v_{out}$ .  
In this case, it means connecting all the neighbors of  $v$  to both  $v_{in}$  and  $v_{out}$ .

2. Construct the flow network:

1. Create a source node  $s$ . Connect  $s$  to all the  $m$  start vertices with capacity 1.
2. Create a sink node  $t$ . Connect all the boundary vertices to  $t$  with capacity  $\infty$ .

3. Apply a max flow algorithm on the transformed graph from  $s$  to  $t$ .

if  $f = m$ , then it is possible. Otherwise, no.

---

## Problem 5

---

### Verifier

- Certificate  $y$  is  $k$  subsets from  $D$ .
- Check whether these subsets are mutually disjoint.
- If so, output 1, else output 0.

### If $x$ is yes instance

- Then there exist  $k$  subsets from  $D$  which are mutually disjoint.
- Give  $y$  to  $V$ , and  $V$  outputs 1.

### If $x$ is no instance

- Then every  $k$  subsets from  $D$  which are not mutually disjoint.
- So  $V$  outputs 0, no matter what  $k$  subsets it gets.

### $V$ runs in polytime

- Checking whether these  $k$  subsets are mutually disjoint takes  $O(C_k^2) = O(k^2)$  time.
- 

## Problem 6

---

First prove the problem is in NP.

### Verifier

- Certificate  $y$  is a course schedule.
- Check whether the courses conflict under this schedule by checking the course assignment of each student.
- If so, output 1, else output 0.

## If $x$ is yes instance

- Then there exist a satisfiable schedule that can schedule the courses without conflicts.
- Give  $y$  to  $V$ , and  $V$  outputs 1.

## If $x$ is no instance

- Then every possible schedule cannot schedule the courses without conflicts.
- So  $V$  outputs 0, no matter what schedule it gets.

## $V$ runs in polytime

- Check whether the course assignment of each student conflicts takes  $O(|R||C|)$  time.

Then reduce from the 3-COLOR problem.

Given an undirected graph  $G = (V, E)$  and an integer  $k = 3$ , we construct  $f(\langle G \rangle) = \langle C, S, R \rangle$  as follows:

1.  $|C| = |V|$ . Construct  $C$  with  $|V|$  distinct elements.
2.  $|S| = 3$ .  $S = \{1, 2, 3\}$ .
3. For each edge  $e$  that connects the two vertices  $u$  and  $v$ , make  $\{u, v\} \in R$ .

Our reduction takes polynomial time because:

1. Constructing  $C$  with  $|V|$  distinct elements takes  $O(|V|)$  time.
2. Constructing  $S = \{1, 2, 3\}$  takes  $O(1)$  time.
3. Constructing  $R$  takes  $O(|E|)$  time.

Therefore the whole reduction takes  $O(|V| + |E|)$  time.

Then we prove the correctness of our reduction as follows:

1. Let  $\langle G \rangle$  be a yes-instance of 3-COLOR. Then for each vertex in  $G$ , it has distinct color with any its adjacent vertex. For any pair  $\{u, v\} \in R$ ,  $u$  and  $v$  are adjacent in  $G$ , so they must have different colors. Since the 3 colors are directly mapped to the 3 different time slots in  $S$ , they must have different time, which means that they never conflict.
2. Let  $\langle G \rangle$  be a no-instance of 3-COLOR. Then for any 3-color assignment to  $V$ , there exist at least 2 adjacent vertices  $u, v$  in  $G$  that have the same color. Therefore, the corresponding pair  $\{u, v\} \in R$  must have the same time slot, leading to a conflict.

Hence, this problem of determining whether a conflict-free schedule exists is NP-complete
